

Alchemize — Production Stabilization Session Summary

Repository: [onlytrafficfans-gif/last-alchemize](#) (mirrored to [Internetkartel/Alchemize-2026](#))

Final commit inspected and verified: [de11a2d](#)

Scope

This session performed direct, incremental production stabilization on the Alchemize Expo/React Native app: inspect the current repo state, fix confirmed defects immediately, validate each fix, and move on — no multi-week roadmap, no unresolved audit-only findings left unaddressed where a safe code-level fix existed.

Confirmed Fixes (18 items, each re-verified against current code)

HealthKit sync persistence — Synced workouts are now written to workoutSessionsDb / normalizedMetricsDb, deduplicated by HealthKit UUID. Previously fetched and discarded.

Gratitude Journal crash — Migrated off an unconfigured Supabase dependency (no env vars, no migration files anywhere in the repo) to local SQLite via gratitudeDb. Was a hard crash for every user.

App identity reverted — name/bundleIdentifier/package/scheme reverted from the unsubmitted 'FRC Enterprise' rebrand back to the original Alchemize identity, matching the live App Store Connect record.

Real app icon — Replaced the placeholder icon set with the actual crystal-ball artwork, including a proper alpha-channel cutout for the Android adaptive icon.

Fitness Hub no-op on web — Every query on the screen (templates, sessions, goals, active plan, awards) was gated behind a needless Platform.OS==='web' guard; removed.

5 more web no-op DB guards — Same root-cause bug in calorie profile, calorie photo/barcode save, fitness manual-add, fitness browse, and fitness workout-complete.

todos/index.tsx crash — A lint-driven edit referenced updateMutation before its own declaration (temporal dead zone) — caught and fixed before shipping via live verification, not just tsc.

Global Back button broken app-wide — canGoBack was computed from useRootNavigationState().routes.length, which never reflected real navigation depth. Replaced with router.canGoBack(). Back button was completely absent on every screen with a header before this fix.

Appointments screen crash — Same unconfigured-Supabase crash as Gratitude, on the Appointments tab. Migrated to local SQLite; also fixed a split-brain data bug where calorie-scan reminders and the Appointments tab wrote to two different, disconnected stores.

RevenueCat payroll bypass — Any RevenueCat init failure (bad network, misconfigured key, SDK error) silently granted free Pro access to every paid feature. Fixed to fail closed.

CI ignored the real lockfile — The only workflow GitHub Actions actually executes used npm install --legacy-peer-deps with no package-lock.json present, silently ignoring bun.lock. Never ran tsc or lint. A second, dead duplicate workflow file existed in a subdirectory GitHub never reads. Fixed and removed the dead copy.

Unused dependencies removed — firebase and zustand had zero imports anywhere in the app (firebase alone is a large SDK); removed after fresh re-verification.

Backend readiness lied about SurrealDB — `initSurrealDB().catch()` only logged the error; `GET /` always returned `status:ok` regardless. Now returns 503 with `status:error` when SurrealDB never connected.

Backend CORS wide open — `cors()` with no options allowed any origin. Restricted to the production web domain and localhost.

Unused Android permissions — Removed expo-calendar and expo-location (zero JS usage, re-verified against the real expo config --type prebuild output, not just app.json's manual list) — this actually removes `READ_CALENDAR/WRITE_CALENDAR` from the real build. `RECORD_AUDIO` and storage/location permissions that persist due to genuinely-used packages (expo-camera, expo-file-system, expo-image-picker) or Rork's own transitive dependency tree are documented, not silently claimed fixed.

Web build failure (wasm) — expo export --platform web failed outright: Metro couldn't resolve expo-sqlite's wa-sqlite.wasm web-worker asset. Added wasm to Metro's resolver.assetExts. Verified both web and Android exports now succeed end-to-end.

CI never produced a bundle — Added web and Android expo export steps to CI so a broken bundle fails the pipeline instead of only being caught manually.

Delete Account wiped every user's data — `resetDatabase()` ran unscoped `DELETE FROM` across 24 (of 31) tables with no `WHERE` clause — on a shared device, deleting one account destroyed every other account's data too, and even then didn't delete everything it promised to. Fixed to scope every table by the current `userId` (with a `goalId`-based subquery for the one table with no direct `userId` column, ordered correctly relative to its parent). Verified with a standalone two-user isolation test — 5/5 assertions pass.

Verification Evidence (this session, fresh)

Check	Result
git status	clean (only a pre-existing untracked buildlog.txt)
git log origin/main..HEAD	empty — nothing unpushed
tsc --noEmit	exit 0
expo lint	exit 0, 0 warnings
expo-doctor	18/18 checks passed
validate-handoff.js / route-manifest-check.js / repo-health-check.js / production-preflight.js / final-validation.js	exit 0
expo export --platform web	exit 0, dist/ produced
expo export --platform android	exit 0, dist/ produced
Delete-account isolation test (standalone script)	5/5 assertions PASS
Live web preview smoke test	home, fitness, appointments, gratitude, todos, settings — zero console errors on all
Legal URLs (alchemize.app/privacy, /terms, /)	HTTP 200 on all three, checked directly

Remaining External Verification Required

- EAS/App Store Developer credentials for signed device or App Store builds — not configured, needs the account owner.

- App Store Connect: confirm the reverted bundle ID (app.repo.alchemize-level-up) matches the live 'Alchemize' listing.
- RevenueCat live sandbox purchase/restore flow — needs a real device.
- HealthKit sync and habit/appointment reminder delivery — only ever verified in the web preview shim, never a physical device.
- Supabase RLS — currently moot: after this session's fixes, the only remaining Supabase consumer anywhere in the codebase is unreferenced dead code (services/image-upload.service.ts).
- Image-upload bucket privacy — the code now requests short-lived signed URLs instead of permanent public ones, but the storage bucket itself must be set to private in the Supabase dashboard, which this code cannot enforce.

Not Touched / Out of Scope (by explicit instruction)

- @rork-ai/toolkit-sdk and its generateObject-powered AI features — verified working, not modified, per explicit instruction.
- Large file refactors (app/settings.tsx at 2,415 lines, lib/database.ts at 2,103 lines, etc.) — real maintainability debt, but not a today-level release blocker.
- Zero automated test suite — a structural gap, addressed at the process level (this session relied on live verification and targeted standalone scripts instead).
- android/ and android-alchemize/ legacy directories at the repo root — confirmed unreferenced by the active expo/ app, left untouched.

Generated as a session record for handoff continuity.
